# CS 106X
Lecture 26: Inheritance and Polymorphism in C++

Monday, March 13, 2017

Programming Abstractions (Accelerated)
Winter 2017
Stanford University
Computer Science Department

Lecturer: Chris Gregg
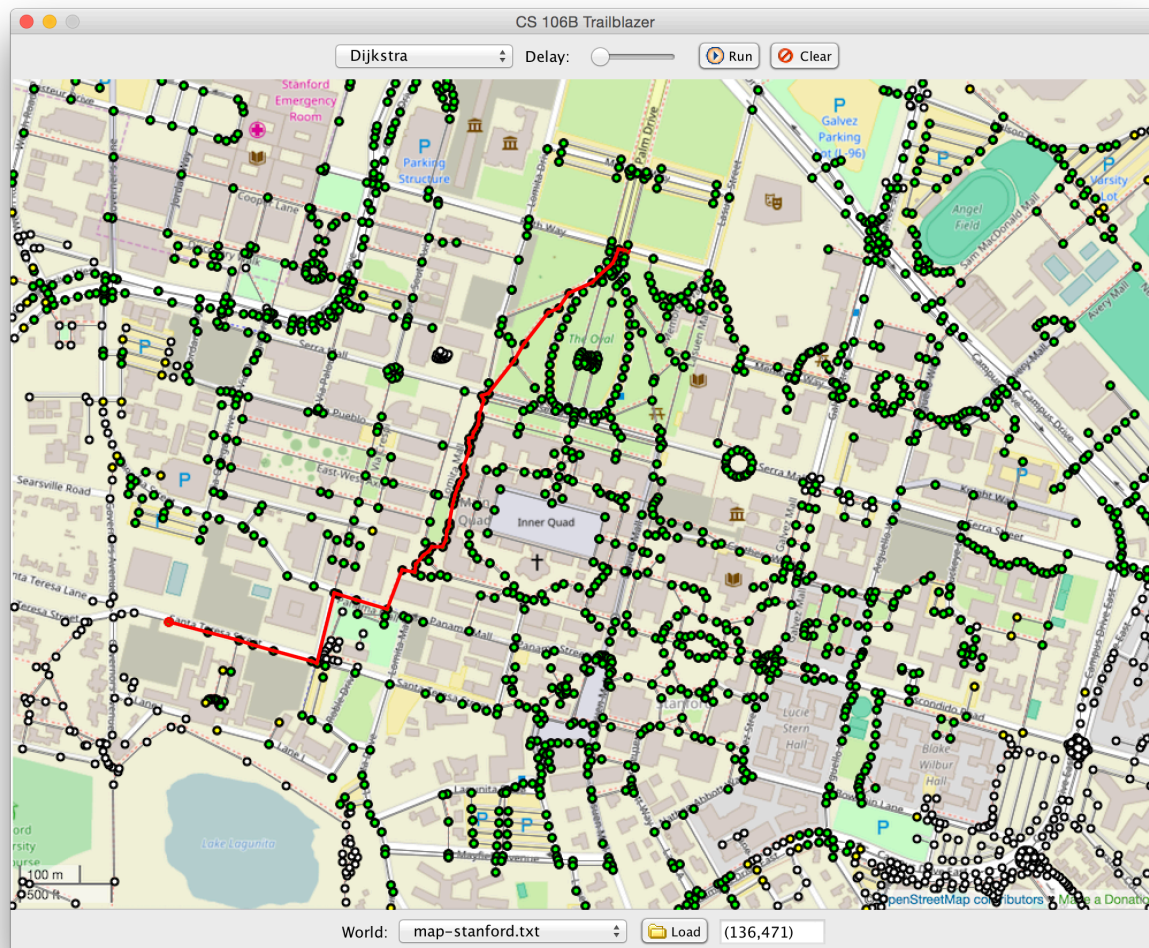

reading:
Programming Abstractions in C++, Chapter 19

Today's Topics

- Logistics
  - Final Exam prep online: http://web.stanford.edu/class/cs106x/handouts/final.html
  - Final exam is on Monday, March 20th at 8:30am.
  - Course evaluations now open on Axess

- A bit more on A*
- Inheritance and Polymorphism in C++

Trailblazer

Road Map Node

Road Map Path Cost
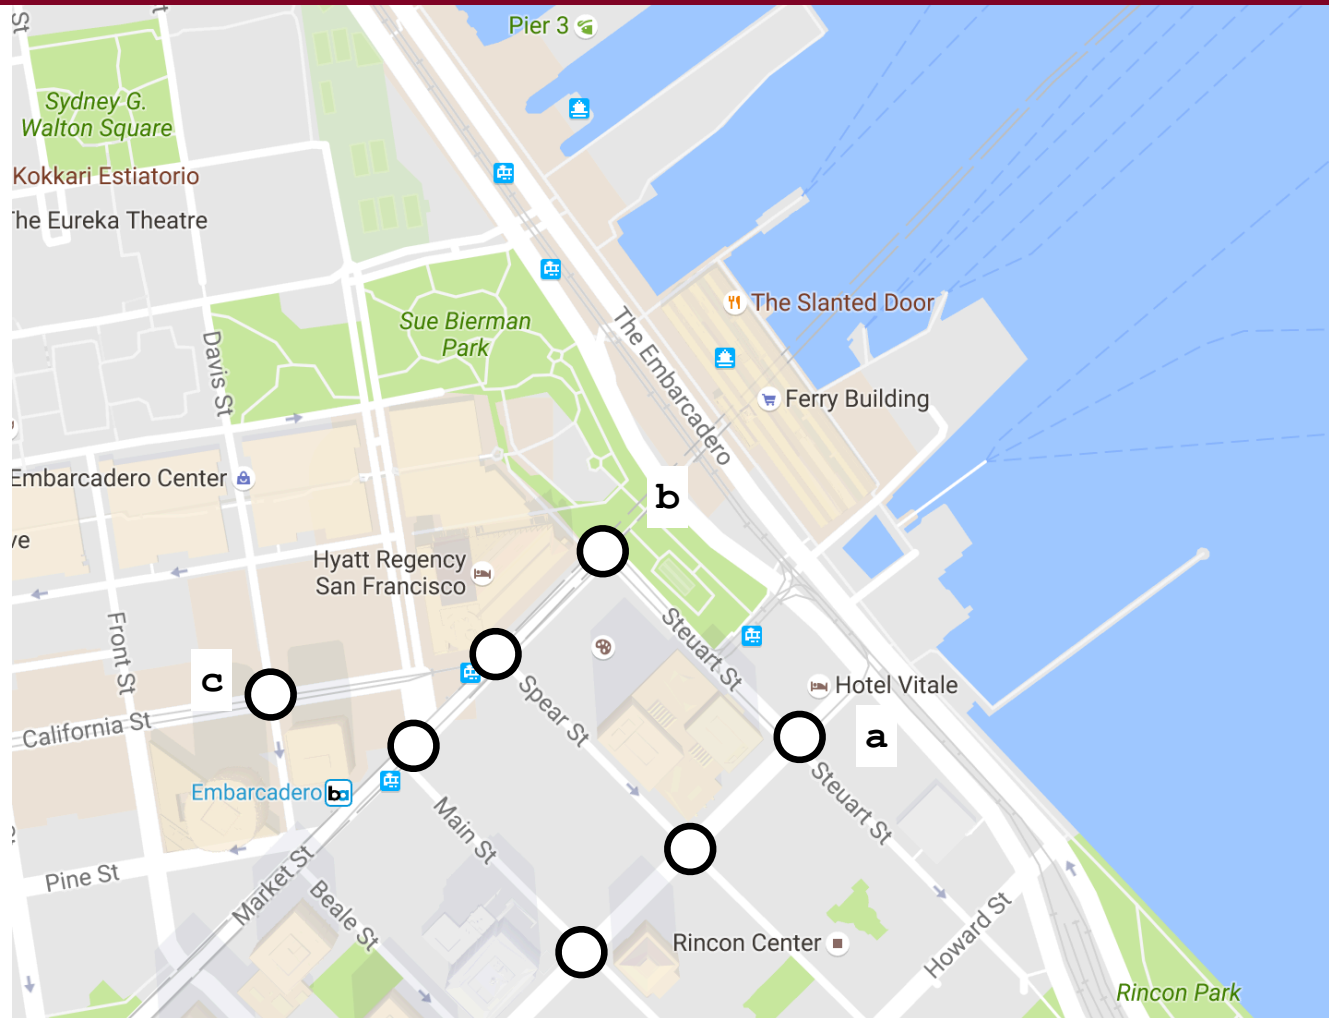

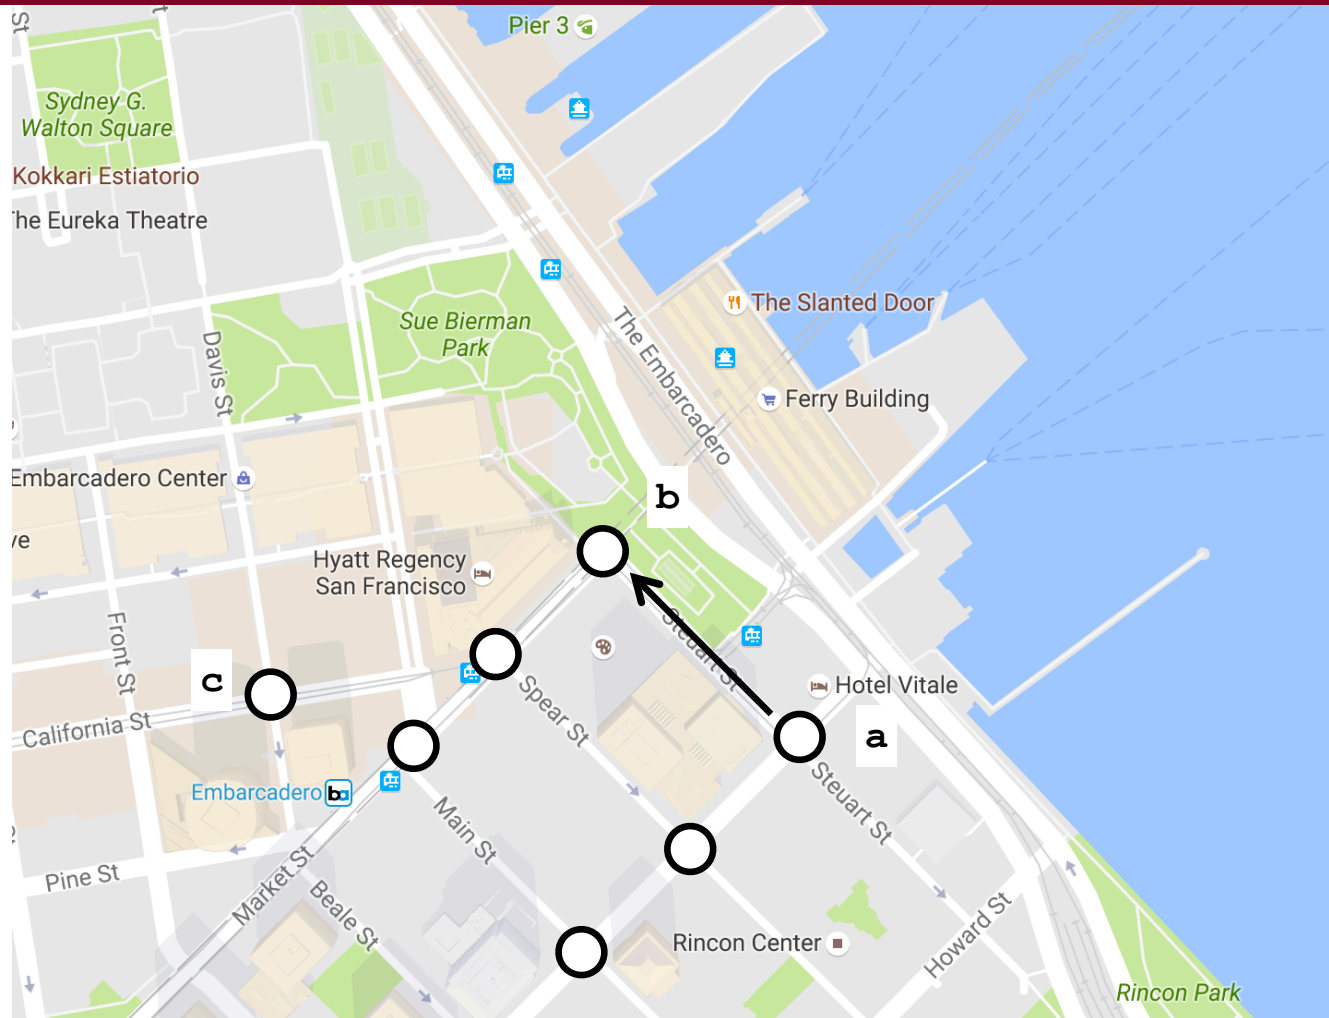

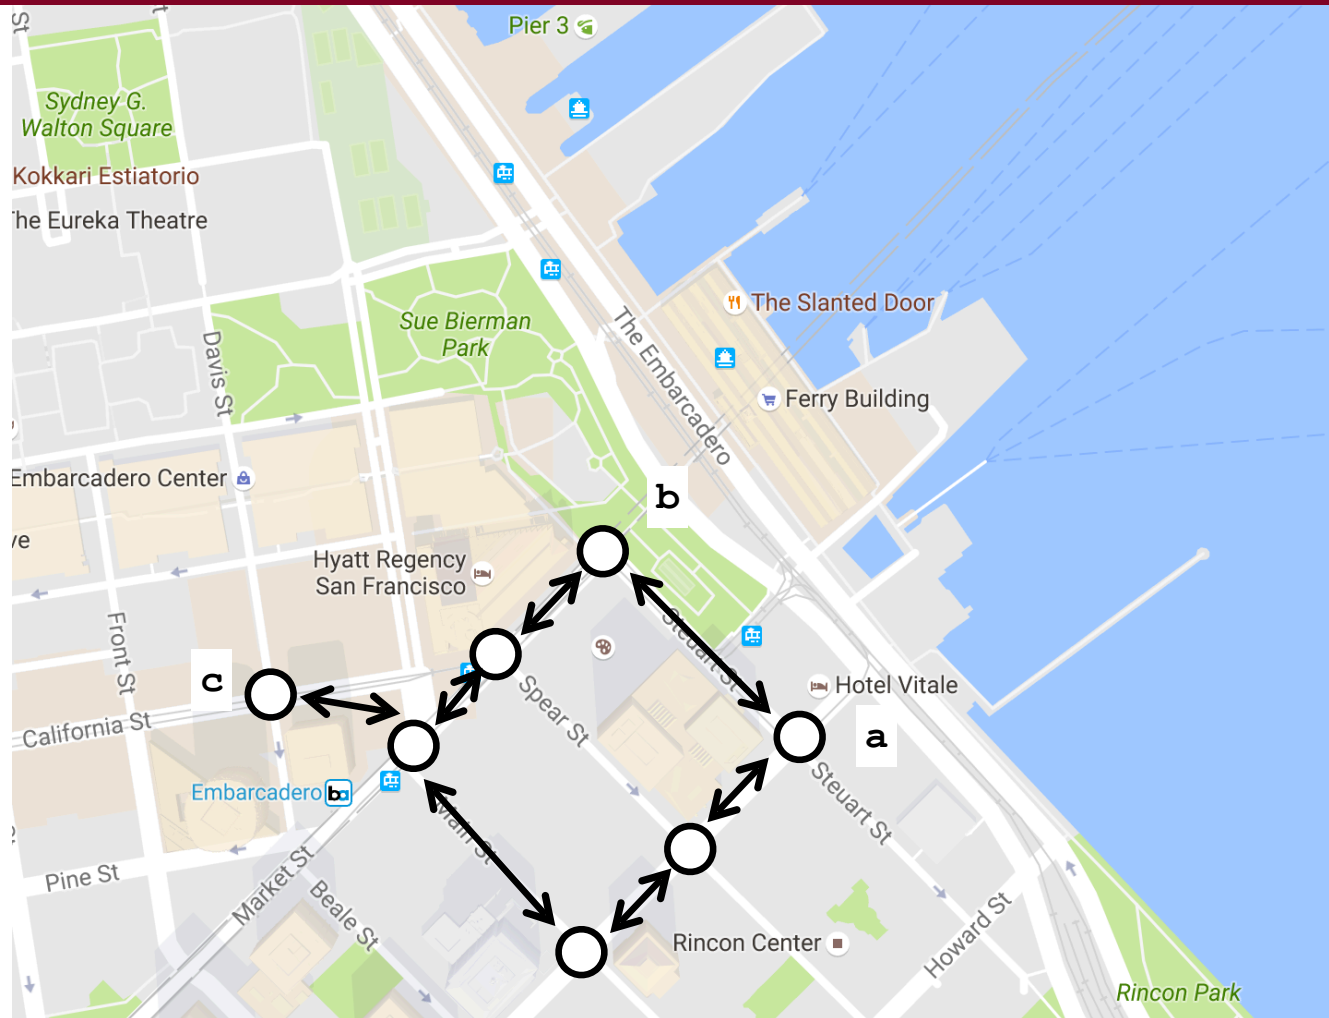

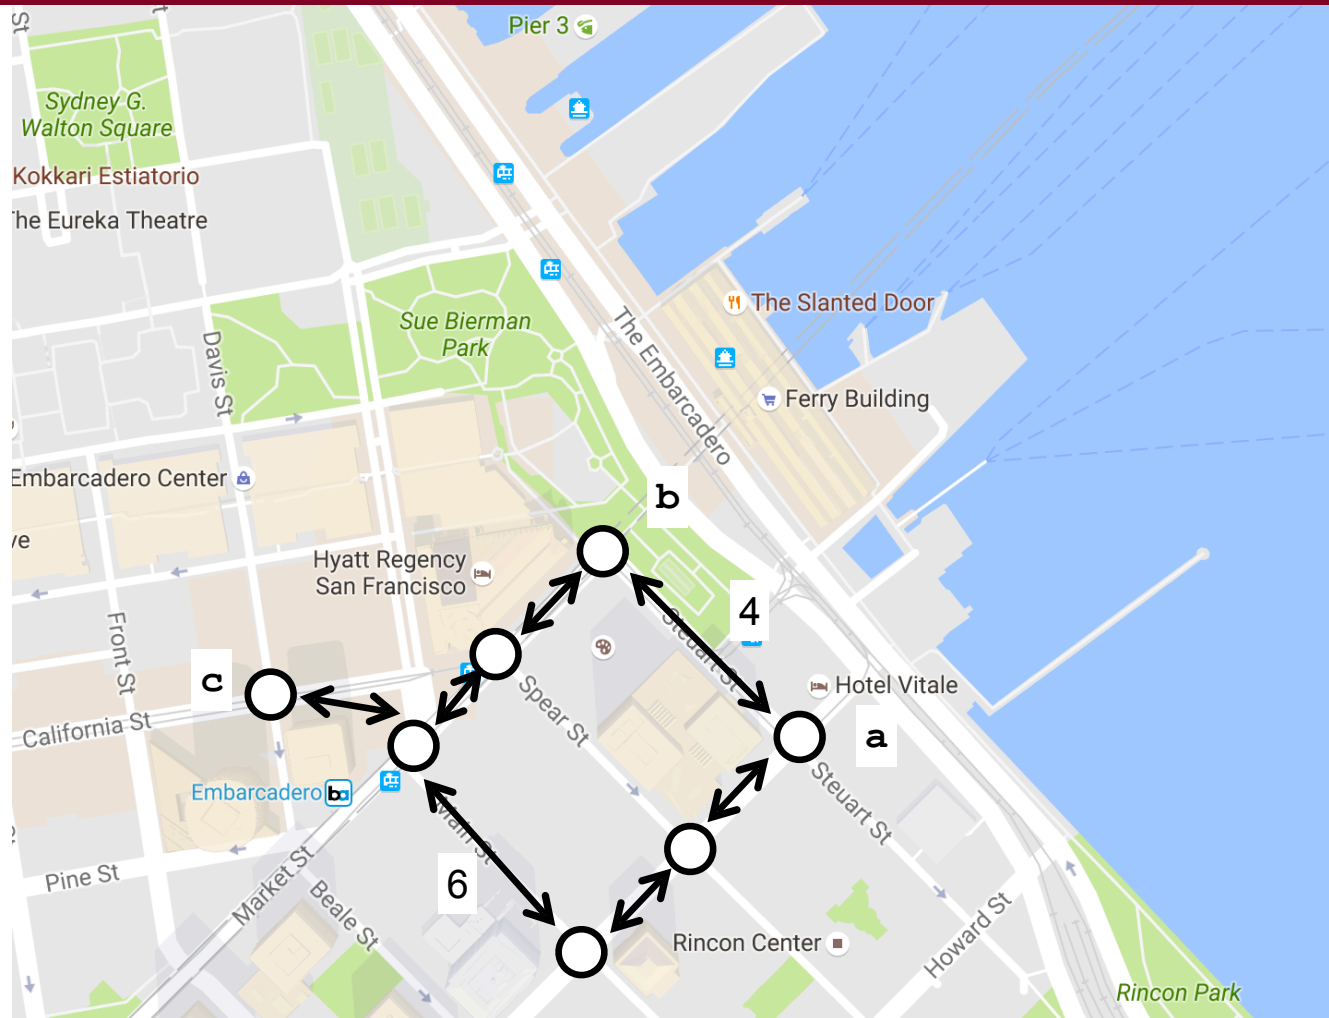

pathCost = 14
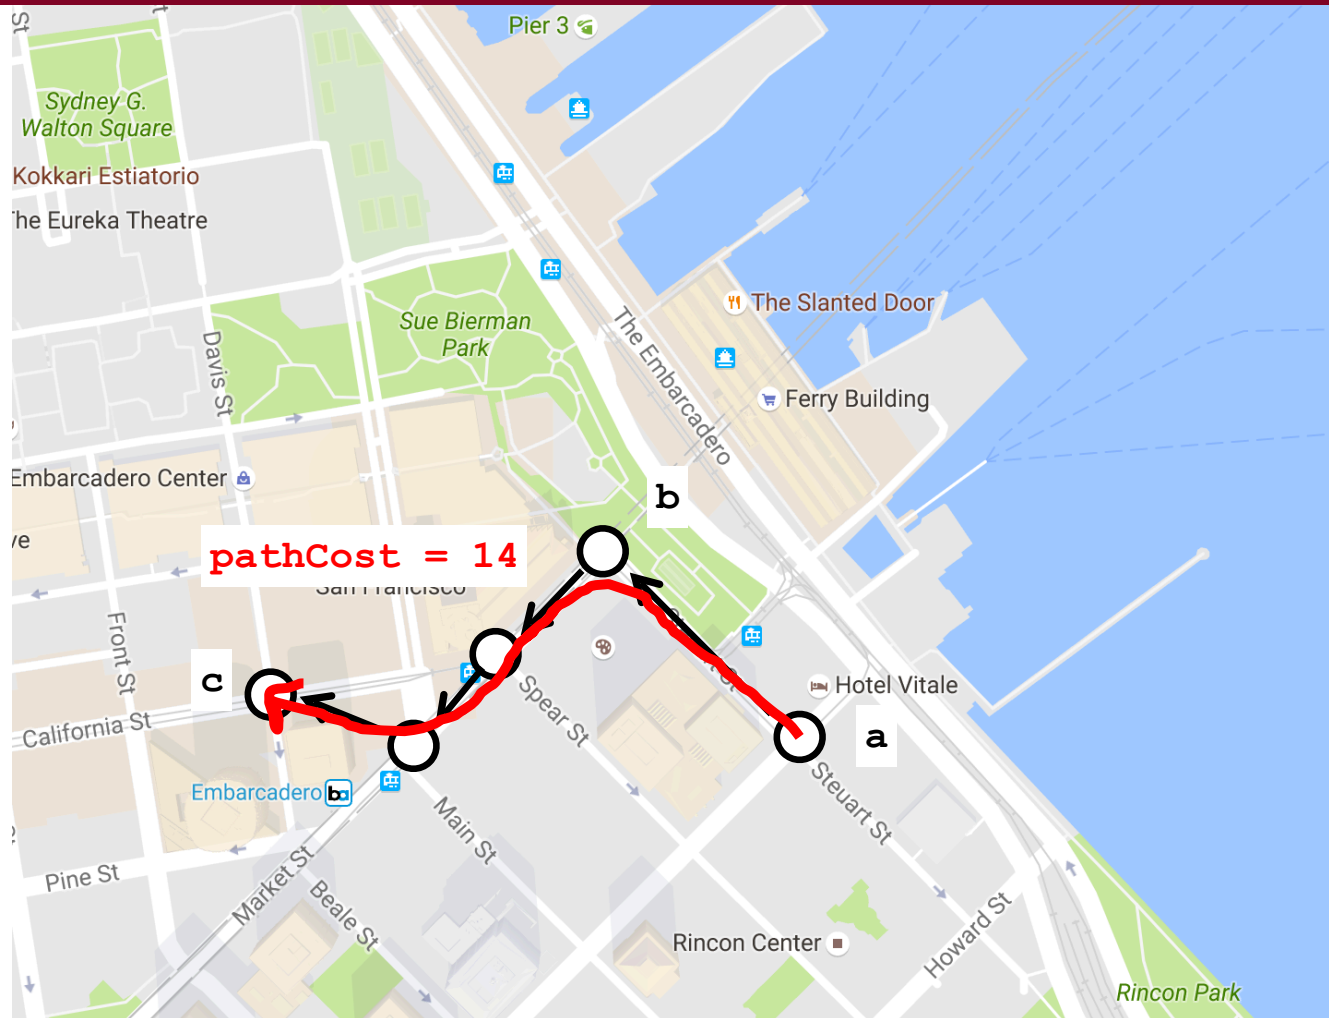

Could Google Just Precompute?

How many nodes in google maps graph?

~ 75 million

$$n^2$$

$$6 \times 10^{15}$$

1 petasecond = 31.7 million years

Can you think of a heuristic?

Road Map Heuristic
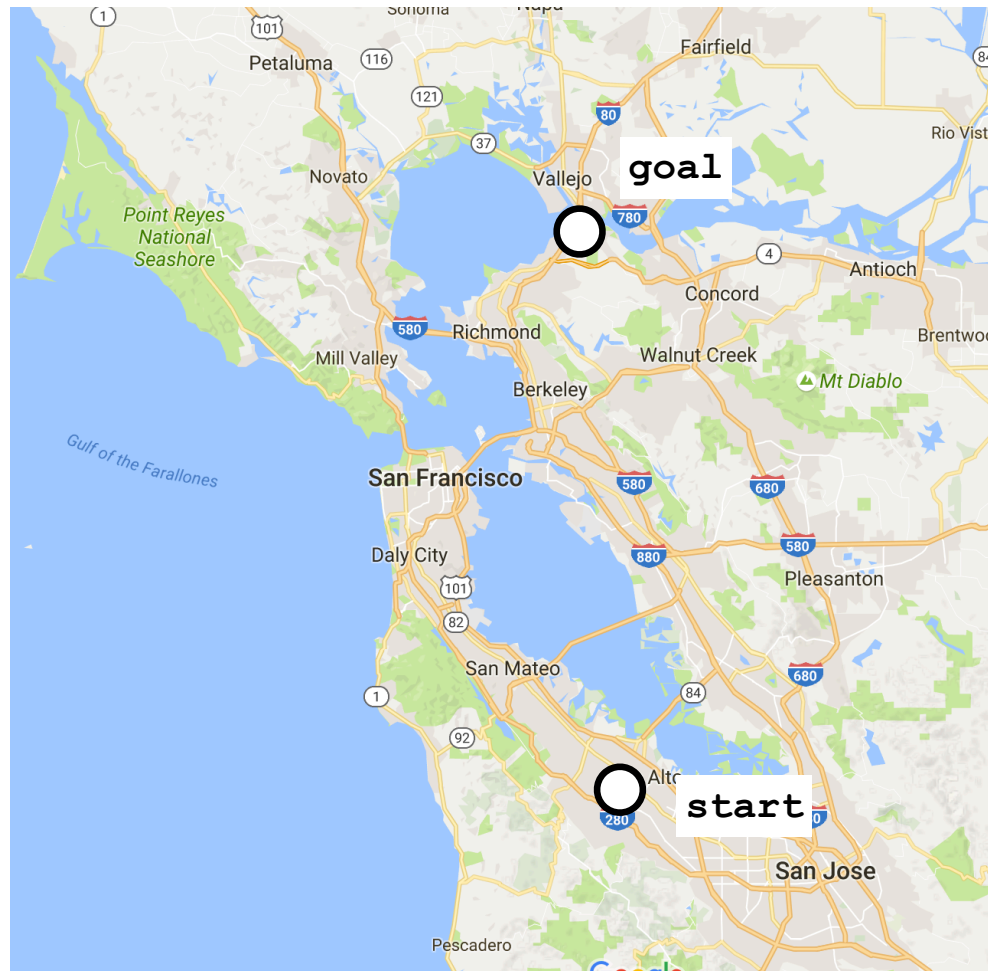

Road Map Heuristic
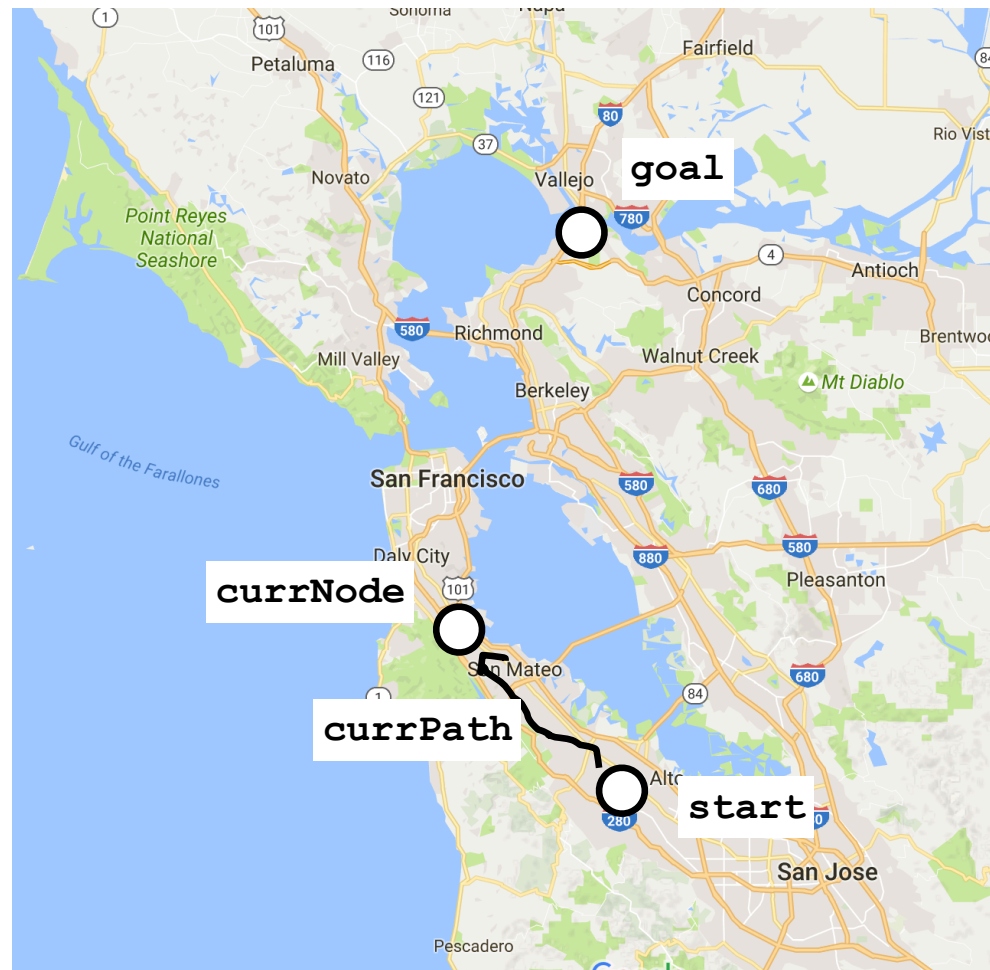

We must *underestimate* this time
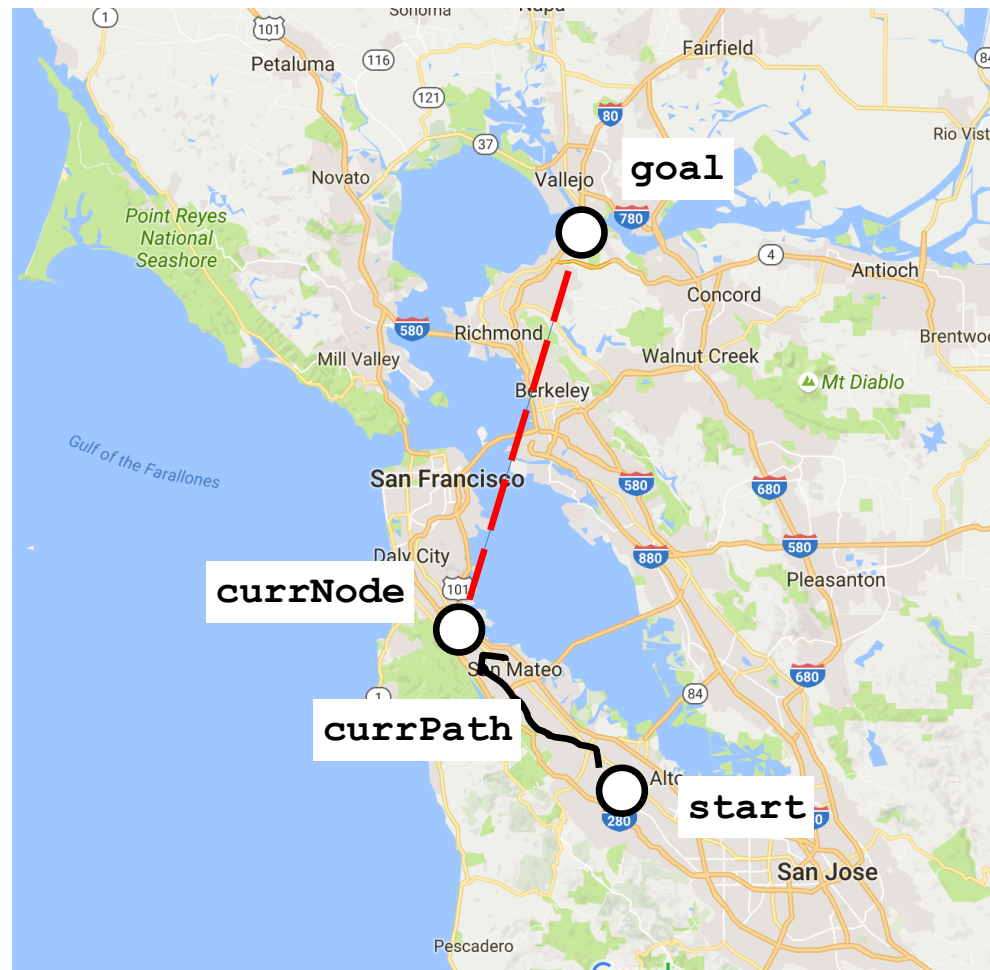

$$\text{Heuristic} = \frac{\text{Distance on surface of earth}}{\text{Speed on fastest highway}}$$

For Trailblazer:
Distance on surface of earth is `getCrowFlyDistance()`
Speed on fastest highway is `getMaxRoadSpeed()`

L

Distance < abs($A - B$)

$$h = \max(h_1, h_2, ..., h_n)$$

priority(u) = distance(s, u) + heuristic(u, t)

distance(s,u)   **heuristic(u,t)**

s → *u* ⟶ Underestimate of Future cost

We want to underestimate the cost of our heuristic, by why?
Let's look at the bounds of our choices:

heuristic(u,t) = 0
heuristic(u,t) = underestimate
heuristic(u,t) = perfect distance
heuristic(u,t) = overestimate

priority(u) = distance(s, u) + heuristic(u, t)

distance(s,u)　　　　**heuristic(u,t)**

s　　　　u　　　　t

We want to underestimate the cost of our heuristic, by why?
Let's look at the bounds of our choices:

heuristic(u,t) = 0
heuristic(u,t) = underestimate
heuristic(u,t) = perfect distance
heuristic(u,t) = overestimate

Same as Dijkstra
priority(u) = distance(s, u) + heuristic(u, t)

distance(s,u)   **heuristic(u,t)**

s   u   t

We want to underestimate the cost of our heuristic, by why?
Let's look at the bounds of our choices:

heuristic(u,t) = 0
heuristic(u,t) = underestimate
heuristic(u,t) = perfect distance
heuristic(u,t) = overestimate

Will be the same or faster than Dijkstra, and will find the shortest path (this is the only "admissible" heuristic for A*.
priority(u) = distance(s, u) + heuristic(u, t)

distance(s,u)   heuristic(u,t)

s   u   t

We want to underestimate the cost of our heuristic, by why?
Let's look at the bounds of our choices:

heuristic(u,t) = 0
heuristic(u,t) = underestimate
heuristic(u,t) = perfect distance
heuristic(u,t) = overestimate

Will only follow the best path, and will find the best path fastest (but requires perfect knowledge)
priority(u) = distance(s, u) + heuristic(u, t)

distance(s,u)   **heuristic(u,t)**

s   u   t

We want to underestimate the cost of our heuristic, by why?
Let's look at the bounds of our choices:

heuristic(u,t) = 0
heuristic(u,t) = underestimate
heuristic(u,t) = perfect distance
heuristic(u,t) = overestimate

**Won't necessarily find
shortest path (but might run
even faster)**

Definition: An admissible heuristic always underestimates the true cost.

Could you precompute this for all your vertices? Yes, but it would not be feasible.

inheritance: A way to form new classes based on existing classes, taking on their attributes/behavior.

- a way to indicate that classes are related
- a way to share code between two or more related classes (a **hierarchy**)
One class can *extend* another, absorbing its data/behavior.
- **superclass** (base class): Parent class that is being extended.
- **subclass** (derived class): Child class that inherits from the superclass.
  - Subclass gets a copy of every field and method from superclass.
  - Subclass can add its own behavior, and/or change inherited behavior.

29

GObject Hierarchy

The Stanford C++ library contains a hierarchy of graphical objects based on a common base class named `GObject`.

- `GArc, GCompound, GImage, GLabel, GLine, GOval, GPolygon, GRect, G3DRect, GRoundRect, ...`
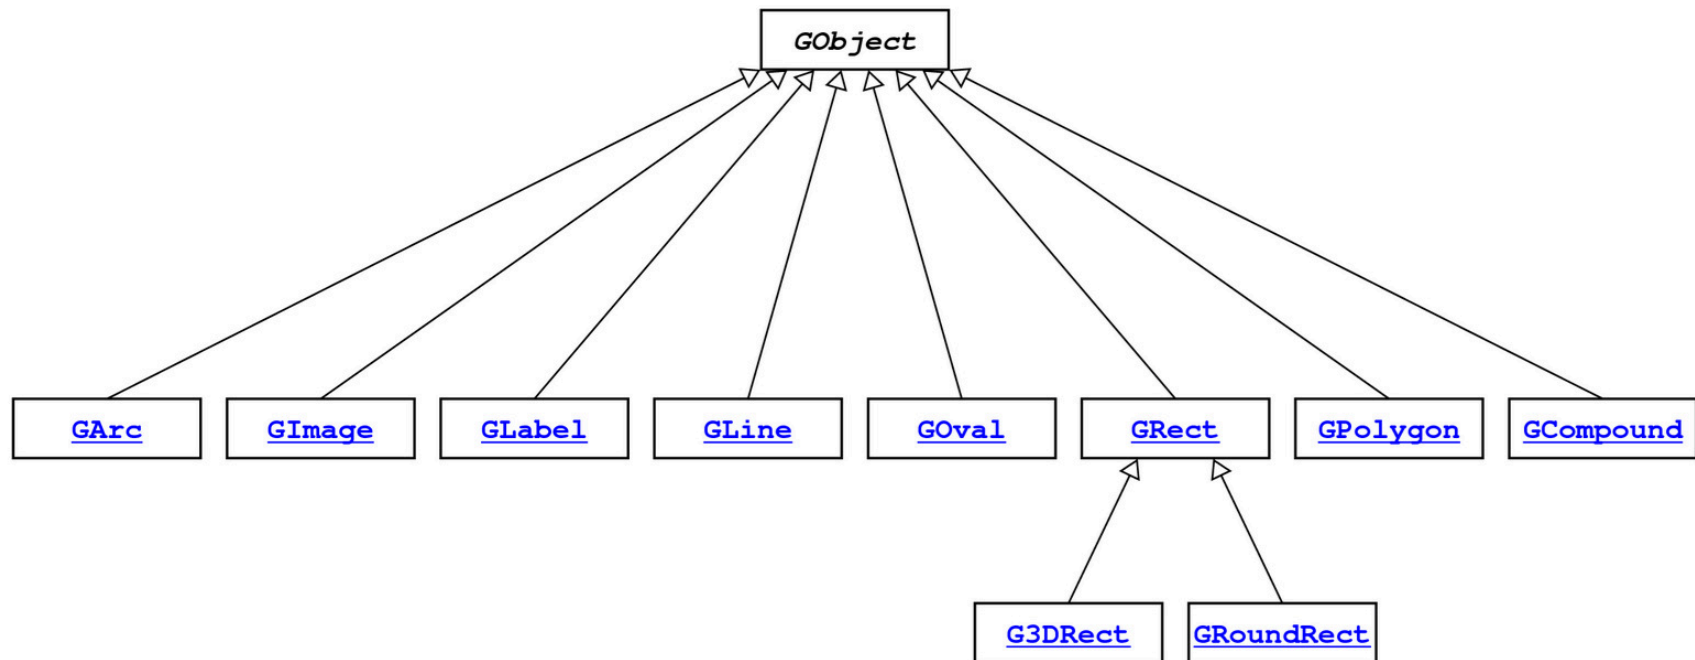

`GObject` defines the state and behavior common to all shapes:

- `contains(x, y)`
- `getColor(), setColor(color)`
- `getHeight(), getWidth(), getLocation(), setLocation(x, y)`
- `getX(), getY(), setX(x), setY(y), move(dx, dy)`
- `setVisible(visible)`
- `toString()`

The subclasses add state and behavior unique to them:

```
GLabel:              GLine:                GPolygon:
· get/setFont        · get/setStartPoint   · addEdge
· get/setLabel       · get/setEndPoint     · addVertex
·                    ·                     · get/setFillColor
· ...                · ...                 · ...
```

Imagine a company with the following **employee regulations**:

- All employees work 40 hours / week.

- Employees make $40,000 per year plus $500 for each year worked,

  - except for lawyers who get twice the usual pay,

    and programmers who get the same $40k base but $2000 for each year worked.

- Employees have 2 weeks of paid vacation days per year,

  - except for programmers who get an extra week (a total of 3).

- Employees should use a yellow form to apply for leave,

  - except for programmers who use a pink form.

Each type of employee has some unique behavior:

- **Lawyers** know how to sue.
- **Programmers** know how to write code.
- **Secretaries** know how to take dictation.
- **Legal Secretaries** know how to take dictation and how to file legal briefs.

Employee Class

```cpp
// Employee.h
class Employee {
public:
    Employee(string name, int years);
    virtual int hours() const;
    virtual string name() const;
    virtual double salary() const;
    virtual int vacationDays() const;
    virtual string vacationForm() const;
    virtual int years() const;

private:
    string myName;
    int myYears;
};
```

```cpp
// Employee.cpp
Employee::Employee(string name, int years) {
    myName = name;
    myYears = years;
}

int Employee::hours() const {
    return 40;
}

string Employee::name() const {
    return myName;
}

double Employee::salary() const {
    return 40000.0 + (500 * myYears);
}

int Employee::vacationDays() const {
    return 10;
}

string Employee::vacationForm() const {
    return "yellow";
}

int Employee::years() const {
    return myYears;
}
```

Exercise: Implement classes Lawyer and Programmer.

Lawyer

- A Lawyer remembers what **law school** he/she went to.
- Lawyers make twice as much **salary** as normal employees.
- Lawyers know how to **sue** people (unique behavior).

Programmer

- Programmers make the same base salary as normal employees, but they earn a **bonus of $2k/year** instead of $500/year.
- Programmers fill out the **pink form** rather than yellow for vacations.
- Programmers get **3 weeks of vacation** rather than 2.
- Programmers know how to write **code** (unique behavior).

Overriding

- **override**: To replace a superclass's member function by writing a new version of that function in a subclass.
- **virtual function**: One that is allowed to be overridden.
  - Must be declared with `virtual` keyword in superclass.

```
// Employee.h
virtual string vacationForm();
```

```
// Employee.cpp
string Employee::vacationForm() {
    return "yellow";
}
```

```
// Programmer.h
virtual string vacationForm();
```

```
// Programmer.cpp
string Programmer::vacationForm() {
    return "pink";   // override!
}
```

If you "override" a non-virtual function, it actually just puts a second copy of that function in the subclass, which can be confusing later.

 * Virtual has some subtleties. For example, destructors in inheritance hierarchies should always be declared virtual or else memory may not get cleaned up properly; ugh.

```
SubclassName::SubclassName(params) : SuperclassName(params) {
    statements;
}
```

To call a superclass constructor from subclass constructor, use an *initialization list*, with a colon after the constructor declaration.

Example:
```
Lawyer::Lawyer(string name, string lawSchool, int years) :
          Employee(name, years) {
    // calls Employee constructor first
    mylawSchool = lawSchool;
}
```

`SuperclassName::memberName(params)`

To call a superclass overridden member from subclass member.

Example:
```
double Lawyer::salary() { // paid twice as much
    return Employee::salary() * 2;
}
```

Notes:
- Subclass cannot access private members of the superclass.
- You only need to use this syntax when the superclass's member has been overridden.
- If you just want to call one member from another, even if that member came from the superclass, you don't need to write `Superclass::` .

Lawyer.h

```cpp
#pragma once

#include "Employee.h"
#include <string>

class Lawyer : public Employee {
    // I now have an hours, name, salary, etc. method. yay!
public:
    Lawyer(string name, string lawSchool, int years);
    virtual double salary() const;
    void sue(string person);

private:
    string myLawSchool;
};
```

```cpp
#include "Lawyer.h"

// call the constructor of Employee superclass?
Lawyer::Lawyer(string name, string lawSchool, int years)
: Employee(name, years) {
    myLawSchool = lawSchool;
}

// overriding: replace version from Employee class
double Lawyer::salary() const {
    return Employee::salary() * 2;
}

void Lawyer::sue(string person) {
    cout << "See you in court, " << person << endl;
}
```

Perils of Inheritance (i.e., think before you inherit!)

Consider the following places you might use inheritance:
- class `Point3D` extends `Point2D` and adds z-coordinate
- class `Square` extends `Rectangle` (or vice versa?)
- class `SortedVector` extends `Vector`, keeps it in sorted order
What's wrong with these examples? Is inheritance good here?
- `Point2D`'s `distance()` function is wrong for 3D points
- `Rectangle` supports operations a `Square` shouldn't (e.g. `setWidth`)
- `SortedVector` might confuse client; they call insert at an index, then check that index, and the element they inserted is elsewhere!

class Name : private SuperclassName { ...

private inheritance: Copies code from superclass but does not publicly advertise that your class extends that superclass.
- Good for cases where you want to inherit another class's code, but you don't want outside clients to be able to randomly call it.
- Example: Have `Point3D` privately extend `Point2D` and add z-coordinate functionality.
- Example: Have `SortedVector` privately extend `Vector` and add only the public members it feels are appropriate (e.g., no `insert`).

Pure Virtual Functions

virtual **returntype name(params)** = 0;

pure virtual function: Declared in superclass's .h file and set to 0 (null). An absent function that has not been implemented.
· Must be implemented by any subclass, or it cannot be used.
· A way of forcing subclasses to add certain important behavior.

```
class Employee {
    ...
    virtual void work() = 0;  // every employee does
                              // some kind of work
};
```

FYI: In Java, this is called an *abstract method*.

Multiple Inheritance

class **Name** : public **Superclass1**, public **Superclass2**, ...

multiple inheritance: When one subclass has multiple superclasses.
- Forbidden in many OO languages (e.g. Java) but allowed in C++.
- Convenient because it allows code sharing from multiple sources.
- Can be confusing or buggy, e.g. when both superclasses define a member with the same name.

Example: The C++ I/O streams use multiple inheritance:
Polymorphism

polymorphism: Ability for the same code to be used with different types of objects and behave differently with each.

- Templates provide *compile-time* polymorphism. Inheritance provides *run-time* polymorphism.

Idea: Client code can call a method on different kinds of objects, and the resulting behavior will be different.

Shape
draw() erase()

Circle	Square	Triangle
draw() erase()	draw() erase()	draw() erase()
Polymorphism and Pointers

A pointer of type *T* can point to any subclass of *T*.

```
Employee* edna = new Lawyer("Edna", "Harvard", 5);
Secretary* steve = new LegalSecretary("Steve", 2);
World* world    = new WorldMap("map-stanford.txt");
```

When a member function is called on edna, it behaves as a Lawyer.
- (This is because the employee functions are declared virtual.)
- You can *not* call any `Lawyer`-only members on `edna` (e.g. `sue`).
  You can *not* call any `LegalSecretary`-only members on `steve` (e.g. `fileLegalBriefs`).

Polymorphism Example

You can use the object's extra functionality by casting.

```
Employee* edna = new Lawyer("Edna", "Harvard", 5);
edna->vacationDays();                       // ok
edna->sue("Stuart");                        // compiler error
((Lawyer*) edna)->sue("Stuart");            // ok
```

You should not cast a pointer to something that it is not.

- It will compile, but the code will crash (or behave unpredictably) when you try to run it

```
Employee* paul = new Programmer("Paul", 3);
paul->code();                               // compiler
error
((Programmer*) paul)->code();               // ok
((Lawyer*) paul)->sue("Marty");             // crash!
```

Polymorphism Mystery

```cpp
class Snow {
public:
    virtual void method2() {
        cout << "Snow 2" << endl;
    }
    virtual void method3() {
        cout << "Snow 3" << endl;
    }
};

class Rain : public Snow {
public:
    virtual void method1() {
        cout << "Rain 1" << endl;
    }
    virtual void method2() {
        cout << "Rain 2" << endl;
    }
};
```

```cpp
class Sleet : public Snow {
public:
    virtual void method2() {
        cout << "Sleet 2" << endl;
        Snow::method2();
    }
    virtual void method3() {
        cout << "Sleet 3" << endl;
    }
};

class Fog : public Sleet {
public:
    virtual void method1()   {
        cout << "Fog 1" <<   endl;
    }
    virtual void method3()   {
        cout << "Fog 3" <<   endl;
    }
};
```
```
Snow* var1 = new Sleet();
var1->method2(); // What's the output?
```

To find the behavior/output of calls like the one above:

1. Look at the variable's type.
   If that type does not have that member: COMPILER ERROR.

2. Execute the member.
   Since the member is virtual: behave like the object's type,
   not like the variable's type.

Example 1

variable

Q: What is the result of
the following call?

Snow* var1 = new Sleet();
var1->method2();

A. Snow 2

B. Rain 2

C. Sleet 2
   Snow 2

D. COMPILER ERROR

Snow

method2()
method3()

Snow 2
Snow 3

object

Rain

method1()
method2()
(method3())

Rain 1
Rain 2
Snow 3

Sleet

method2()
method3()

Sleet 2 / Snow 2
Sleet 3

Fog

method1()
method2()
method3()

Fog 1
Sleet 2 / Snow 2
Fog 3

Example 2

Q: What is the result of
the following call?

`Snow* var2 = new Rain();`
`var2->method1();`

variable

object

A. `Snow 1`

B. `Rain 1`

C. `Snow 1`
   `Rain 1`

D. `COMPILER ERROR`

Snow
- `method2()` — Snow 2
- `method3()` — Snow 3

Rain
- `method1()` — Rain 1
- `method2()` — Rain 2
- `(method3())` — Snow 3

Sleet
- `method2()` — Sleet 2 / Snow 2
- `method3()` — Sleet 3

Fog
- `method1()` — Fog 1
- `method2()` — Sleet 2 / Snow 2
- `method3()` — Fog 3
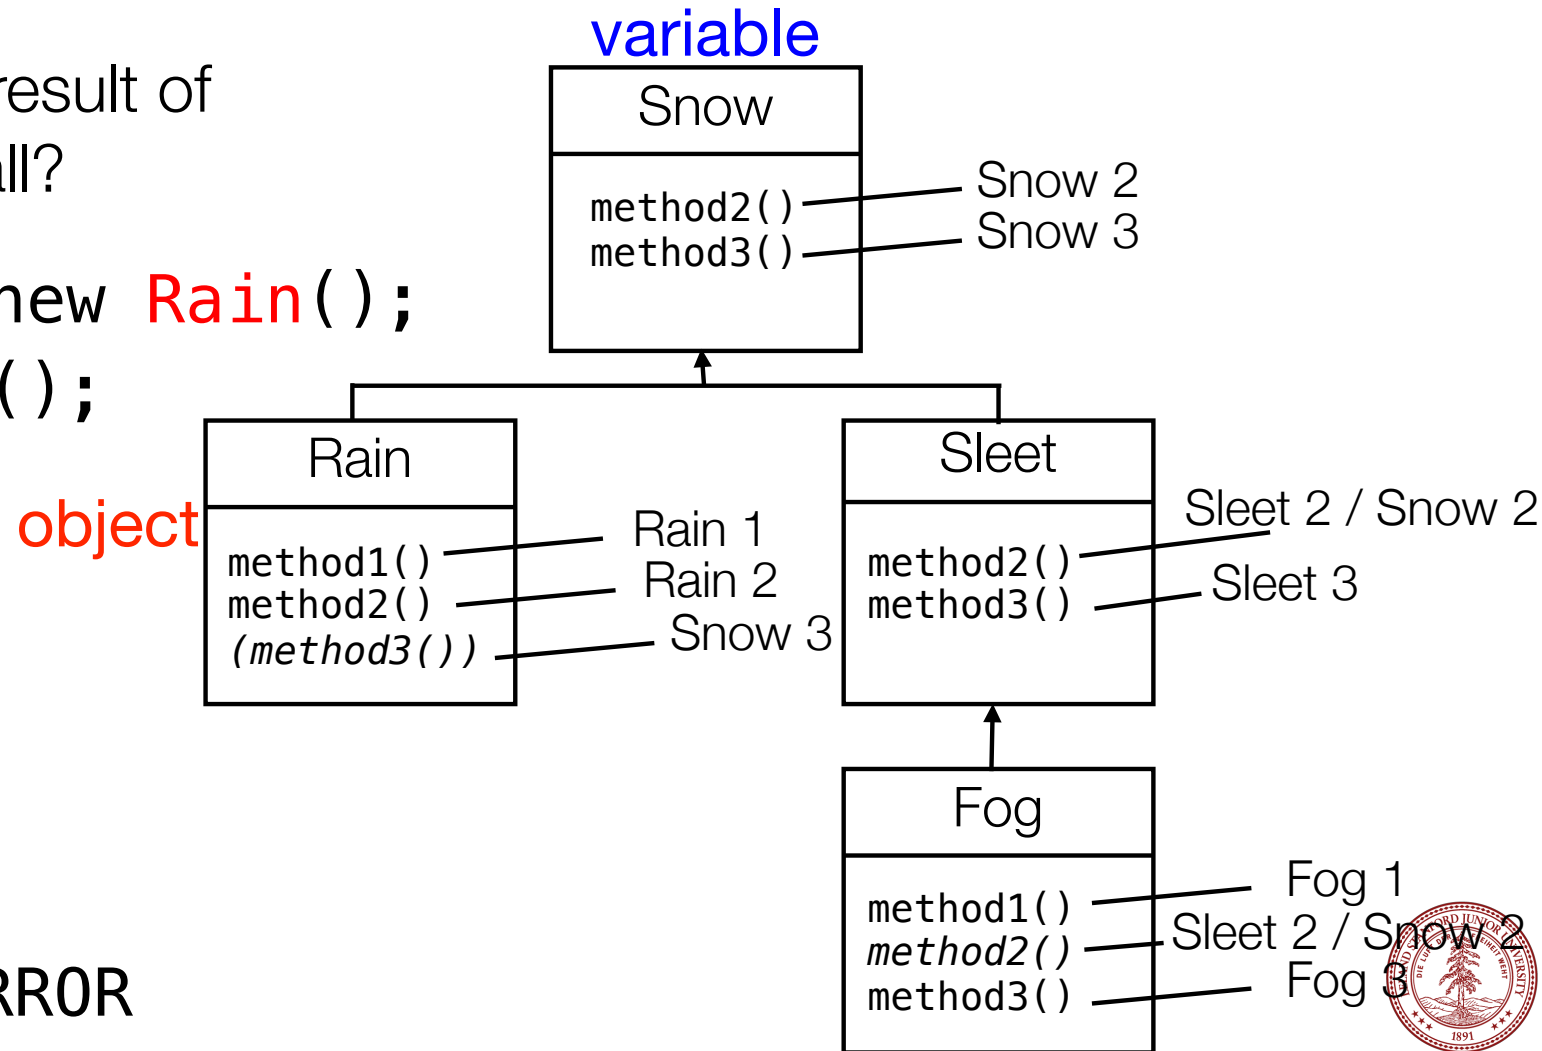

Example 3

Q: What is the result of the following call?

`Snow* var3 = new Rain();`

`var3->method2();`

A. `Snow 2`

B. `Rain 2`

C. `Sleet 2`
   `Snow 2`

D. `COMPILER ERROR`

variable

```
Snow
```
```
method2()    Snow 2
method3()    Snow 3
```

object

```
Rain
```
```
method1()      Rain 1
method2()      Rain 2
(method3())    Snow 3
```

```
Sleet
```
```
              Sleet 2 / Snow 2
method2()
method3()     Sleet 3
```

```
Fog
```
```
method1()     Fog 1
method2()     Sleet 2 / Snow 2
method3()     Fog 3
```
```
Snow* var4 = new Rain();
((Rain *) var4->method1(); // What's the output?
```

If the mystery problem has a type cast, then:

1. Look at the cast type.
   If that type does not have the method: COMPILER ERROR.

   (Note: if the object's type was not equal to or a subclass of the cast type, the code would CRASH / have unpredictable behavior.)

2. Execute the member.
   Since the member is virtual: behave like the object's type, not like the variable's type.
Example 4

Q: What is the result of
the following call?

Snow* var4 = new Rain();
((Rain *) var4)->method1();

variable

```
┌─────────────────┐
│      Snow       │
├─────────────────┤
│  method2()      │── Snow 2
│  method3()      │── Snow 3
└─────────────────┘
```

cast
object

```
┌─────────────────┐        ┌─────────────────┐
│      Rain       │        │      Sleet      │
├─────────────────┤        ├─────────────────┤
│  method1()      │─ Rain 1│  method2()      │── Sleet 2 / Snow 2
│  method2()      │─ Rain 2│  method3()      │── Sleet 3
│  (method3())    │─ Snow 3└─────────────────┘
└─────────────────┘
```

A. Snow 1

B. Rain 1

C. Sleet 1

```
┌─────────────────┐
│      Fog        │
├─────────────────┤
│  method1()      │── Fog 1
│  method2()      │── Sleet 2 / Snow 2
│  method3()      │── Fog 3
└─────────────────┘
```
D. COMPILER ERROR

Example 5

Q: What is the result of the following call?

```
Snow* var5 = new Fog();
((Sleet *) var5)->method1();
```

variable

Snow

method2() — Snow 2
method3() — Snow 3

A. `Snow 1`

B. `Sleet 1`

C. `Fog 1`

D. `COMPILER ERROR`

Rain

method1() — Rain 1
method2() — Rain 2
(method3()) — Snow 3

Sleet cast

method2() — Sleet 2 / Snow 2
method3() — Sleet 3

Fog object

method1() — Fog 1
method2() — Sleet 2 / Snow 2
method3() — Fog 3

Example 6

Suppose we add the following method to base class Snow:

```
virtual void method4() {
    cout << "Snow 4" << endl;
    method2();
}
```

What is the output?

```
Snow* var6 = new Sleet();
var6->method4();
```

Answer:
```
Snow 4
Sleet 2
Snow 2
```

(Sleet's method2 is used because method 4 and method2 are virtual)

variable

Snow
method2() — Snow 2
method3() — Snow 3

object

Rain
method1() — Rain 1
method2() — Rain 2
(method3()) — Snow 3

Sleet
method2() — Sleet 2 / Snow 2
method3() — Sleet 3

| Fog |
|-----|
| method1() — Fog 1 |
| method2() — Sleet 2 / Snow 2 |
| method3() — Fog 3 |

Example 7

What is the output of the following call?

```
Snow* var7 = new Sleet();
((Rain*) var7)->method1();
```

A. `Snow 1`
B. `Sleet 1`

C. `Fog 1`

D. `COMPILER ERROR`

E. `CRASH / UNDEFINED`

variable

Snow
method2() ——— Snow 2
method3() ——— Snow 3

cast

object

Rain
method1() ——— Rain 1
method2() ——— Rain 2
(method3()) ——— Snow 3

Sleet
method2() ——— Sleet 2 / Snow 2
method3() ——— Sleet 3

Fog
method1() ——— Fog 1
method2() ——— Sleet 2 / Snow 2
method3() ——— Fog 3
